## Smartphone-based home care model improved use of cardiac rehabilitation in postmyocardial infarction patients: results from a randomised controlled trial

Marlien Varnfield,<sup>1,2</sup> Mohanraj Karunanithi,<sup>1,3</sup> Chi-Keung Lee,<sup>4</sup> Enone Honeyman,<sup>1</sup> Desre Arnold,<sup>4</sup> Hang Ding,<sup>1</sup> Catherine Smith,<sup>2</sup> Darren L Walters<sup>3,5</sup>

**ABSTRACT**  
**Objective** Cardiac rehabilitation (CR) is pivotal in preventing recurring events of myocardial infarction (MI). This study aims to investigate the effect of a smartphone-based home service delivery (Care Assessment Platform) of CR (CAP-CR) on CR use and health outcomes compared with a traditional, centre-based programme (TCR) in post-MI patients.  
**Methods** In this unblinded randomised controlled trial, post-MI patients were randomised to TCR (n=60; 55.7 ±10.4 years) and CAP-CR (n=60; 55.5±9.6 years) for a 6-week CR and 6-month self-maintenance period. CAP-CR, delivered in participants' homes, included health and exercise monitoring, motivational and educational material delivery, and weekly mentoring consultations. CAP-CR uptake, adherence and completion rates were compared with TCR using intention-to-treat analyses. Changes in clinical outcomes (modifiable lifestyle factors, biomedical risk factors and health-related quality of life) across baseline, 6 weeks and 6 months were compared within, and between, groups using linear mixed model regression.

Studies have demonstrated a 15–28%<sup>1–2</sup> decrease in all-cause mortality. Despite demonstrated benefits and guideline recommendations, CR use has been poor, particularly in women, older patients and ethnic minorities.<sup>3,4</sup> Patient and system barriers have marred CR uptake and adherence, traditionally delivered through group-based exercise programmes in centre-based settings.<sup>5–8</sup> Recent advances in information and communication technologies, such as smartphones and the internet, have shown potential to address some of these barriers through home-based CR programmes<sup>9–10</sup> and remote clinical monitoring and communication.<sup>11</sup> One such model, the Care Assessment Platform (CAP-CR), was recently described.<sup>12</sup> The objective of this study is to investigate whether CAP-CR is effective in improving CR use in post-MI patients compared with a traditional, centre-based programme, while demonstrating equivalent health outcomes, through a randomised controlled trial (RCT).

### REHABILITATION

## Smartphone-based cardiac rehabilitation—a first RCT

The uptake of cardiac rehabilitation (CR) has many barriers, including the time taken to complete a programme and patient reluctance to be involved in group programmes. However, can the growing use of smartphones enable new home-based methods of CR delivery? In the first known randomized, controlled trial of smartphone-delivered CR, investigators report that patient uptake, adherence, and completion of the programme was significantly better using this new technology than with a traditional programme.

"We wanted to investigate whether innovative home-based CR delivery using smartphones and the internet, called the Care Assessment Platform (CAP), could improve the use of CR services and equally provide similar benefits as those of traditional CR programmes," says Dr Mohanraj Karunanithi from the Australian e-Health Research Centre. The team randomly assigned 120 patients with a previous myocardial infarction to receive either traditional CR (TCR; n = 60), which included supervised group exercise and educational session, or cardiac rehabilitation via a smartphone using the CAP (n = 60). Each participant using the CAP received a smartphone with pre-installed software to record a health diary, activity levels, and blood pressure, and receive motivational text, audio, and video messages. Patient uptake of CAP was 80% (n = 48) compared with 62% (n = 37; P < 0.05) for those undertaking TCR. Adherence and overall completion

higher than with TCR (94% vs 68%, and 80% vs 47%, respectively; P < 0.05 for each comparison). Patients receiving TCR were more likely to leave the study owing to competing life demands (work and stress) or logistical reasons (time constraints, transport, or the location of CR appointments) than those using the CAP. Only three patients using the CAP left the study owing to difficulty in using the technology. Importantly, "CAP-CR was an effective as traditional CR programmes in improving physical activity, diet intake, and lowering depression," explains Karunanithi. "The outcomes of this study are already being taken up by Queensland Health, Australia by the implementation of CAP as a validated option within their CR services."

# Lessons learned

- Slow uptake – structural changes
- Providing smartphones and devices
- Services were not structured /staffed for the deployment
- Infrastructure not suitable

- Bring your own device policy
- Ensure buy in from staff and adequate staffing structure
- Train the trainers
- Provide tablet/computers

# Implementation at Metro South HHS

## Centre-based CR programme (access to the smartphone application optional)

Supervised exercise and education sessions over six weeks as per usual care.

Smartphone app optional

CR staff monitor patients' measurements before and after each exercise session (NOT monitored outside the group setting).

## Home-based CR programme supported by smartphone and Internet technologies

Smartphone app for data entry

Patients' measurements are remotely monitored (six weeks) during which they receive a call/week to discuss their progress

Home

Web portal for clinician review prior to weekly phone call

## Flexible (switch-over) CR programme with access to smartphone application

Patients commence in centre-based programme (with access to smartphone app) and switch over to home-based programme dependent on personal circumstances.

# Results

- Two of the services reporting > 10% participation in the home-based programme respectively, none at the 3rd service.
- Few patients selected to partake in the hybrid CR offering.
- Home-based patients were generally younger ( $58 \pm 9$  years) vs ( $64 \pm 11$  years).
- Improvement in functional capacity and Heart QoL in all programs

Our plan...
