T1 mapping

Předkontrastně:

- přesné stanovení T1 relaxačního času myokardu
- 950 ± 21 ms (pro přístroje o síle 1,5 Tesla)
- zvýšení: edém myokardu, přítomnosti fibrózy či infiltrace amyloidem
- snížení: Fabryho choroba, sideróza

Postkontrastně:

- ECV (extracelulární objem/frakce): podíl extracelulárního objemu k celkovému objemu myokardu LK
- přítomnost fibrózy (difuzní) či amyloidu (nepoužívá se pro detekci edému).
- pro výpočet je nutné měřit T1 relaxační čas myokardu a krve před a 15 minut po podání kontrastní látky a také znát aktuální hodnotu hematokritu
- normální hodnota ECV je $0,25 \pm 0,04$ (1,5 Tesla)

*statistically different ($p < 0.05$); ^{††}no statistical difference ($p = ns$). T1-mapping: myocardial injury is detected when T1 is ≥ 990 ms; Dark-blood T2-weighted imaging: edema is diagnosed when the T2 SI ratio ($T2\ SI_{myocardium} : skeletal\ muscle$) is $\geq 2:1$; Late gadolinium enhancement (LGE) is detected when myocardial SI is ≥ 2 SD above mean SI of remote myocardium. For each technique, only contiguous areas of myocardium $\geq 40\ mm^2$ above the stated threshold were considered relevant; involvement of $\geq 5\%$ of any segment on a per-subject basis was the threshold used for comparison of methods. PPV = positive predictive value; NPV = negative predictive value.

- využití stejné jako pro T2W obrazy
- přesnější v diagnostice zánětlivé KMP
