3. Jaké jsou terapeutické možnosti ovlivnění afterloadu/preloadu pravé komory a její morfologie/funkce a jak můžeme pravou komoru monitorovat?
4. Je reverzní remodelace pravé komory dostatečný terapeutický cíl plicní arteriální hypertenze?

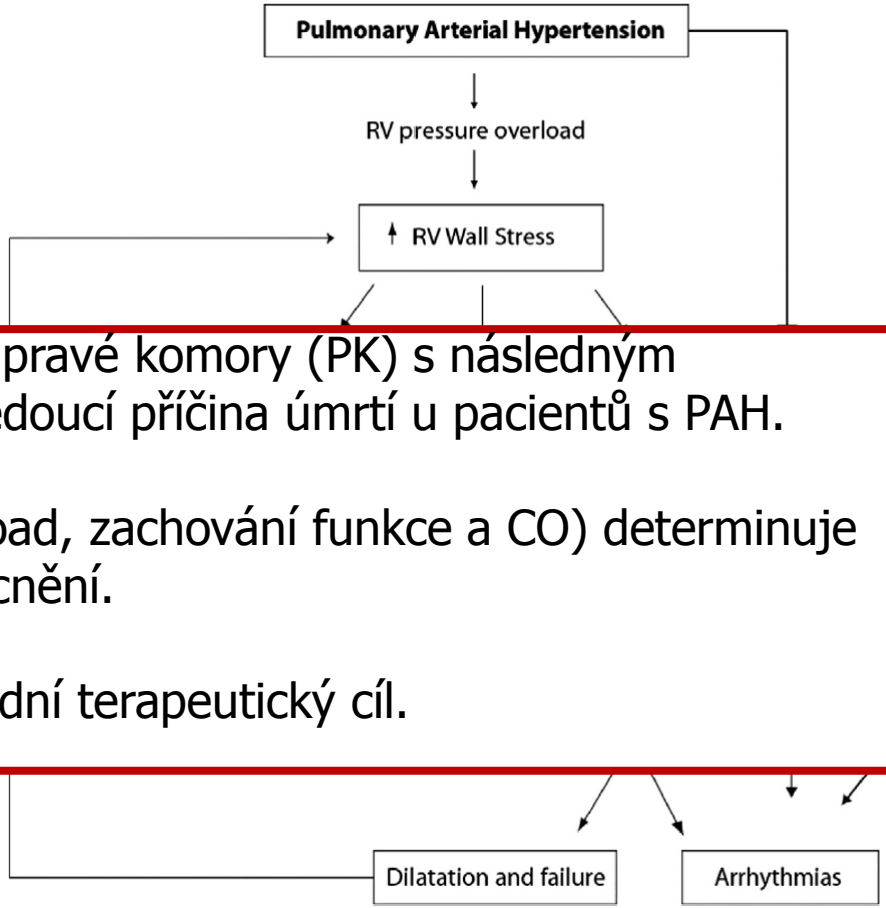
Pravá komora u PAH

- An **afterload mismatch** - increased RV afterload, driven by increased PVR, leads to right heart failure.
- At an early stage, the RV adapts to the increased afterload to preserve stroke volume (**homeometric adaptation**), followed by an **heterometric adaptation** when the latter gets exhausted



- Vyčerpání kompenzačních mechanismů pravé komory (PK) s následným pravostranným srdečním selháním je vedoucí příčina úmrtí u pacientů s PAH.
- Funkce PK (adaptace na zvýšený afterload, zachování funkce a CO) determinuje funkční status a klinický průběh onemocnění.
- Zachování/zlepšení funkce PK jako zásadní terapeutický cíl.

Table 12 Recommendations for the echocardiographic assessment of RA size

Parameter and method	Echocardiographic imaging	Advantages	Limitations
Linear dimensions. The minor axis of the right atrium should be measured in the apical four-chamber view as the distance between the lateral RA wall and interatrial septum, at the midatrial level defined by half of RA long axis	2D-guided linear measurements 	• Easy to obtain • Established normal values	• Single dimension only • Assumes that RA enlargement is symmetrical • View dependent
Area. Measured in the apical four-chamber view at end-systole, on the frame just prior to tricuspid valve opening, by tracing the RA blood-tissue interface, excluding the area under the tricuspid valve annulus.	2D view 	• More representative of actual RA size than linear dimensions • Established normal values	• Need of a dedicated view to avoid RA foreshortening • Assumes a symmetrical shape of the cavity • View dependent

POSITION PAPER

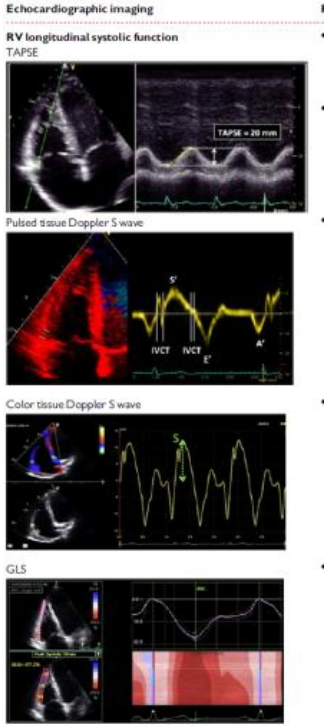
Recommendations for Cardiac Chamber Quantification by Echocardiography in Adults: An Update from the American Society of Echocardiography and the European Association of Cardiovascular Imaging

Tricuspid annular plane systolic excursion (TAPSE) reflects longitudinal shortening of the RV. TAPSE is measured in the A4C by placing an M-mode cursor on the lateral tricuspid annulus and measuring the peak distance travelled by this reference point during systole. A greater distance travelled during systole implies greater RV systolic function, with the normal reference limit being a TAPSE of ≥1.7 cm.

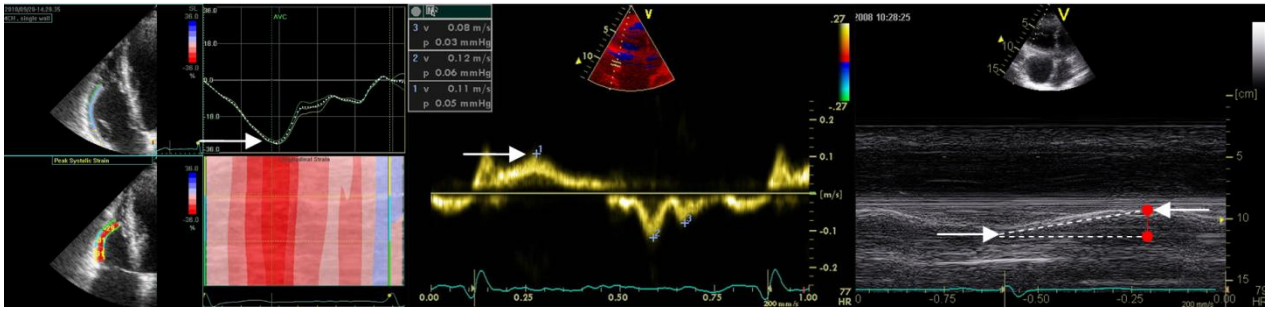
The primary limitation of TAPSE is that it only represents one component of RV motion within one single segment of RV myocardium. The RV may be frankly dysfunctional despite relatively preserved TAPSE, as in some cases of severe pulmonary arterial hypertension. Alternatively, the RV function may be globally preserved despite significantly reduced TAPSE, as often seen after cardiac surgery. In healthy individuals, TAPSE correlates with RV size.

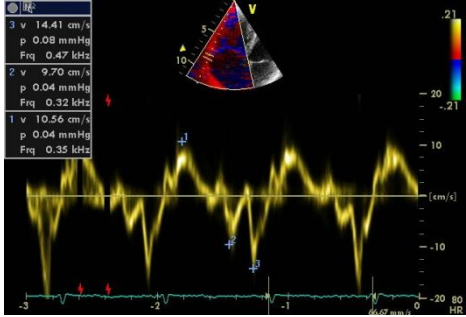
Two common sources of error with TAPSE are:

1. Not placing the M-mode cursor parallel to the plane of longitudinal motion, which results in angle-dependent underestimation of TAPSE.
2. Incorrectly measuring the magnitude of displacement from the M-mode image.



Lang RM, Badano LP, Mor-Avi V, et al. Recommendations for cardiac chamber quantification by echocardiography in adults: an update from the American Society of Echocardiography and the European Association of Cardiovascular Imaging. J Am Soc Echocardiogr. 2015;28(1):1.





Tricuspid annular velocity reflects the longitudinal velocity of the tricuspid annulus during systole.

S' is measured in the A4C by placing a tissue Doppler cursor on the lateral tricuspid annulus and measuring the peak velocity of this reference point during systole. Care should be taken to measure the peak of the ejection waveform and not the earlier isovolumetric contraction waveform.

A greater velocity during systole implies greater RV systolic function, with the **normal reference limit** being an S' of ≥9.5 cm/s. Both pulsed tissue Doppler and color-coded tissue Doppler can be used to measure S', although the color-coded method yields mean velocities that are usually slightly lower.

The **advantages and limitations** are the same as TAPSE:

1. S' is simple to perform and has prognostic data, yet it is angle-dependent and only represents the longitudinal annular component of RV motion.
2. S' has been shown to correlate with CMR-derived RVEF and predicts outcomes in patients with pulmonary hypertension, inferior myocardial infarction, chronic heart failure, and arrhythmogenic RV cardiomyopathy (ARVC).

Lang RM, Badano LP, Mor-Avi V, et al. Recommendations for cardiac chamber quantification by echocardiography in adults: an update from the American Society of Echocardiography and the European Association of Cardiovascular Imaging. J Am Soc Echocardiogr. 2015;28(1):1.

Frakční změna plochy PK

Fractional area change (FAC) is the % change in RV area from diastole to systole, a two-dimensional surrogate for RV EF, and thereby reflects the systolic function of the inflow and apical portions of the RV. FAC encompasses longitudinal shortening as well as radial thickening and the contribution of the septum.

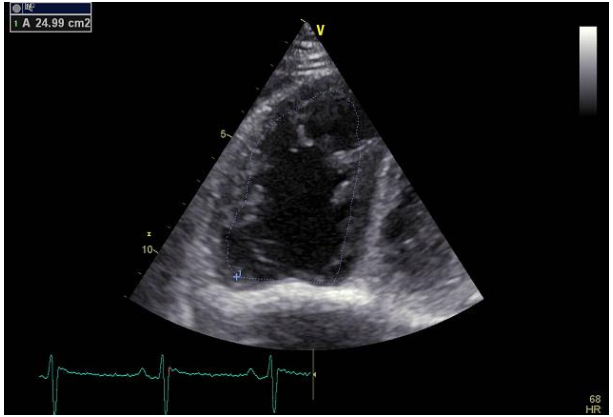
FAC = [(end-diastolic RV area – end-systolic RV area)/end-diastolic RV area] x 100

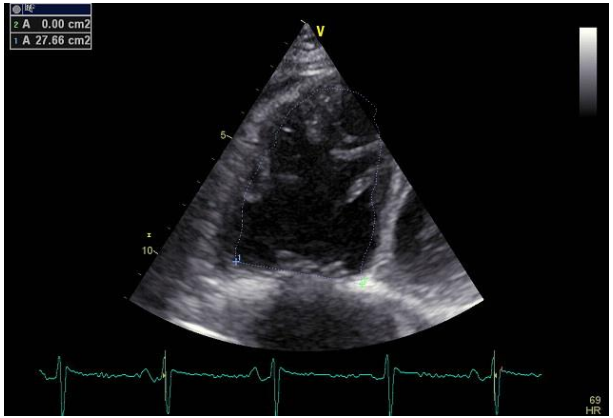
The normal reference limit for FAC is ≥35%.

The primary challenge and main limitation of FAC is the accurate tracing of the true RV endocardial border.

Compared with TAPSE and S', FAC was found to correlate best with the reference standard of CMR-derived RVEF *(r=0.80)*.

1. In substudies from the SAVE and VALIANT trials, 416 and 522 patients with **AMI** and evidence of LV dysfunction underwent complete echocardiographic assessment. Four independent predictors of subsequent all-cause mortality were identified: age, Killip classification, LV ejection fraction, and FAC; with FAC <35 percent carrying an adjusted hazard ratio of 3.56.
2. In the **Multidisciplinary Study of Right Ventricular Dysplasia**, FAC was found to be significantly reduced in probands compared with normal controls. The revised ARVC Task Force Criteria list FAC ≤33% as a major diagnostic criterion and FAC 34-40% as a minor criterion





Lang RM, Badano LP, Mor-Avi V, et al. Recommendations for cardiac chamber quantification by echocardiography in adults: an update from the American Society of Echocardiography and the European Association of Cardiovascular Imaging. J Am Soc Echocardiogr. 2015;28(1):1.

Strain PK

2D strain imaging is defined as the % change in myocardial deformation (RV longitudinal shortening). Strain is currently measured principally by the speckle-tracking (non-angle-dependent) approach.

Potential pitfalls include technical challenges in image acquisition and analysis (need for high frame rates, high signal-to-noise, experienced observers for reproducible measurements).

Contemporary speckle-tracking algorithms have enhanced reproducibility and are beginning to yield **clinically relevant** observations:

1. In a large cohort of 575 patients with pulmonary arterial hypertension, free wall longitudinal strain by 2D speckle tracking was predictive of functional capacity and 18-month mortality.
2. In 200 patients with heart failure and seemingly normal RV systolic function (TAPSE >16 mm), a substantial proportion of patients was found to have abnormal RV free wall strain indicative of subclinical RV dysfunction, which was in turn predictive of death and hospitalization.
3. To identify signs of RV infarction in patients presenting with acute myocardial infarction, RV free wall strain was superior to conventional echocardiographic parameters.

The **normal reference limit** for 2DS of the RV free wall is -23%/-20%.

Abstract

Background—

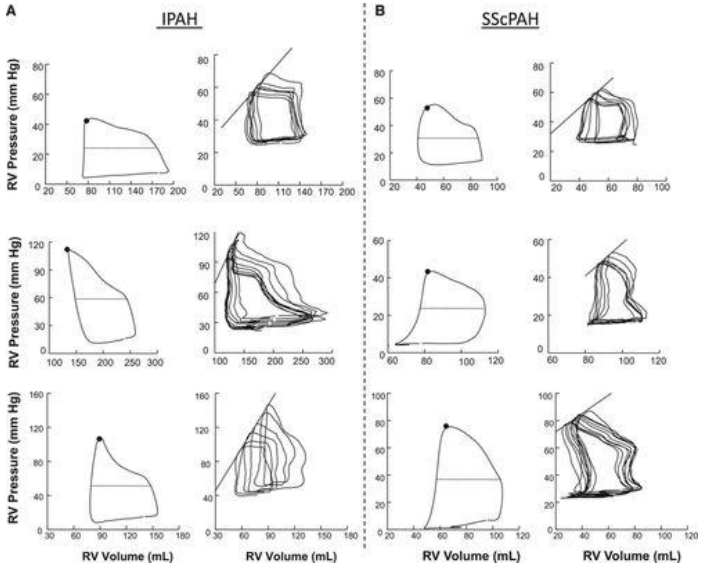
Systemic sclerosis–associated pulmonary artery hypertension (SScPAH) has a worse prognosis compared with idiopathic pulmonary arterial hypertension (IPAH), with a median survival of 3 years after diagnosis often caused by right ventricular (RV) failure. We tested whether SScPAH or systemic sclerosis–related pulmonary hypertension with interstitial lung disease imposes a greater pulmonary vascular load than IPAH and leads to worse RV contractile function.

Methods and Results—

We analyzed pulmonary artery pressures and mean flow in 282 patients with pulmonary hypertension (166 SScPAH, 49 systemic sclerosis–related pulmonary hypertension with interstitial lung disease, and 67 IPAH). An inverse relation between pulmonary resistance and compliance was similar for all 3 groups, with a near constant resistance×compliance product. RV pressure–volume loops were measured in a subset, IPAH (n=5) and SScPAH (n=7), as well as SSc without PH (n=7) to derive contractile indexes (end-systolic elastance [E_{es}] and preload recruitable stroke work [M_{sw}]), measures of RV load (arterial elastance [E_a]), and RV pulmonary artery coupling (E_{es}/E_a). RV afterload was similar in SScPAH and IPAH (pulmonary vascular resistance=7.0±4.5 versus 7.9±4.3 Wood units; E_a=0.9±0.4 versus 1.2±0.5 mm Hg/mL; pulmonary arterial compliance=2.4±1.5 versus 1.7±1.1 mL/mm Hg; P>0.3 for each). Although SScPAH did not have greater vascular stiffening compared with IPAH, RV contractility was more depressed (E_{es}=0.8±0.3 versus 2.3±1.1, P<0.01; M_{sw}=21±11 versus 45±16, P=0.01), with differential RV-PA uncoupling (E_{es}/E_a=1.0±0.5 versus 2.1±1.0; P=0.03). This ratio was higher in SSc without PH (E_{es}/E_a=2.3±1.2; P=0.02 versus SScPAH).

Conclusions—

RV dysfunction is worse in SScPAH compared with IPAH at similar afterload, and may be because of intrinsic systolic function rather than enhanced pulmonary vascular resistive and pulsatile loading.



Right ventricular (RV) pressure–volume loops in 6 patients, 3 with (**A**) idiopathic pulmonary arterial hypertension (IPAH) and 3 with (**B**) systemic sclerosis–associated pulmonary artery hypertension (SScPAH).
Steady-state loops (**left**) in both cohorts show RV pressure rising throughout ejection and peaking at end-systole, consistent with increased RV afterload from PAH. The black dot identifies the end-systolic pressure–volume point, and the dashed line mean loop width (stroke volume).
E_a was determined by the ratio of end-systolic pressure to SV. In the loops generated during Valsalva maneuver (**right**), the data are all shifted upward because of the rise in intrathoracic pressure, but while this is held, phase 2 of the Valsalva maneuver results in a beat-to-beat decline in filling volume, various PV relations including the end-systolic pressure–volume relationship (black line). The slope is end-systolic elastance (E_{es}).

Jaké jsou terapeutické možnosti ovlivnění afterloadu/preloadu pravé komory a její morfologie/funkce a jak můžeme pravou komoru monitorovat?

1. Význam pravé komory u plicní arteriální hypertenze.
2. Jak na hodnocení její funkce a morfologie?
3. **Jaké jsou terapeutické možnosti ovlivnění afterloadu/preloadu pravé komory a její morfologie/funkce a jak můžeme pravou komoru monitorovat?**
4. Je reverzní remodelace pravé komory dostatečný terapeutický cíl plicní arteriální hypertenze?

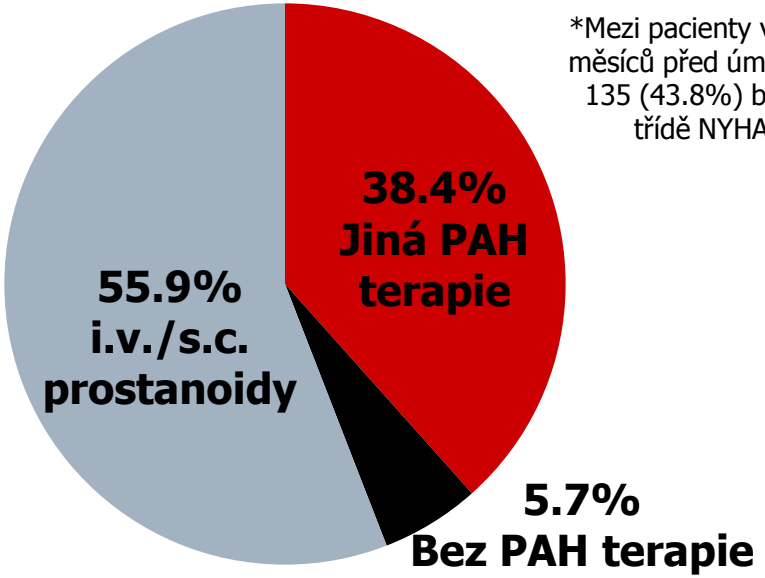
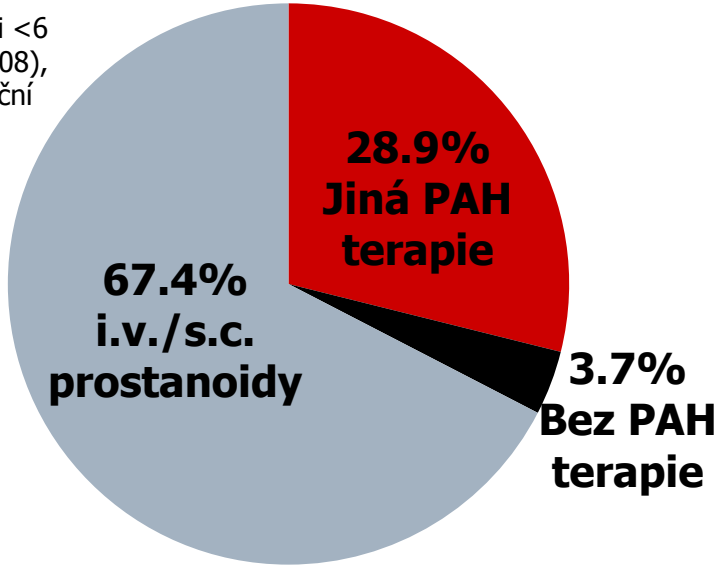
Léčba PAH v době úmrtí

Všichni pacienti (*n* = 487)



*Mezi pacienty vyšetřenými <6 měsíců před úmrtím (*n* = 308), 135 (43.8%) bylo ve funkční třídě NYHA/WHO IV.

NYHA IV* pacienti (*n* = 135)



V době úmrtí souvisejícího s PAH :

- U **všech pacientů**, téměř polovina (44.1%) neužívalo parenterální prostanoidy
- U **NYHA/WHO IV pacientů**, téměř třetina (32.6%) neužívalo parenterální prostanoidy

Odhad systolického tlaku v plicnici - trikuspidální regurgitační gradient

základní parametr pro screening PH pomocí echokardiografie

pro **hodnocení prognózy a rozhodnutí o terapii nemá význam**

vzestup odhadovaného sPAP nemusí nutně ukazovat progresi onemocnění, pokles odhadovaného sPAP nemusí nutně odpovídat zlepšení PAP

invazivně měřený mPAP má rovněž poměrně malý prognostický význam (kromě responderů akutní vazoreaktivity)

Tabulka 4A – Pravděpodobnost zjištění plicní hypertenze echokardiografickým vyšetřením symptomatických pacientů s podezřením na plicní hypertenzi

Maximální rychlost proudu krve při nedomykavosti trojcípé chlopně (m/s)	Přítomnost jiných „známek PH" při echokardiografickém vyšetření[a]	Možnost plicní hypertenze podle echokardiografického vyšetření
≤ 2,8 nebo neměřitelná	Ne	Nízká
≤ 2,8 nebo neměřitelná	Ano	Středně vysoká
2,9–3,4	Ne	
2,9–3,4	Ano	Vysoká
> 3,4	Není nutno provádět

ESC/ERS GUIDELINES

2022 ESC/ERS Guidelines for the diagnosis and treatment of pulmonary hypertension

Developed by the task force for the diagnosis and treatment of pulmonary hypertension of the European Society of Cardiology (ESC) and the European Respiratory Society (ERS).

Endorsed by the International Society for Heart and Lung Transplantation (ISHLT) and the European Reference Network on rare respiratory diseases (ERN-LUNG).

2022 ESC/ERS Guidelines for the diagnosis and treatment of pulmonary hypertension
Supplementary data

A: The ventricles	B: Pulmonary artery	C: Inferior vena cava and RA
RV/LV basal diameter/ area ratio >1.0	RVOT AT <105 ms and/or mid-systolic notching	IVC diameter >21 mm with decreased inspiratory collapse (<50% with a sniff or <20% with quiet inspiration)
Flattening of the interventricular septum (LVEI >1.1 in systole and/or diastole)	Early diastolic pulmonary regurgitation velocity >2.2 m/s	RA area (end-systole) >18 cm^2
TAPSE/sPAP ratio <0.55 mm/mmHg	PA diameter >AR diameter PA diameter >25 mm	

Závěry

1. Vyčerpání kompenzačních mechanismů pravé komory (PK) s následným pravostranným srdečním selháním je vedoucí příčina úmrtí u pacientů s PAH.
2. Funkce PK (adaptace na zvýšený afterload, zachování funkce a CO) determinuje funkční status a klinický průběh onemocnění.
3. Multimodalitní hodnocení morfologie a funkce pravé komory je důležitou součástí každého echokardiografického vyšetření.
4. Dysfunkce PK je u SScPAH ve srovnání s iPAH při identickém afterloadu horší a může být způsobena spíše vlastní systolickou funkcí než zvýšenou rezistencí plicních cév a pulzatilním zatížením. Tato zjištění naznačují klinicky silentní dysfunkci myokardu PK, která může předcházet manifestní PAH a může sloužit jako důležitý cíl pro specifickou léčbu.
5. Zachování/zlepšení funkce PK jako zásadní terapeutický cíl.
